#### ABSTRACT

A therapeutic agent injection device including an injection device for delivering a therapeutic agent to a patient having a body, the body having a patient face and a port face opposite the patient face, the port face having an introducer port including an introducer channel and an injection port including an injection channel, the introducer channel being in fluid communication with the injection channel through a cross channel, the injection channel defining an injection axis; a delivery tube for subcutaneous delivery of the therapeutic agent to the patient, the delivery tube projecting from and being generally perpendicular to the patient face, the delivery tube defining an introducer axis and being in fluid communication with the injection port; and a patch, the patch being attached to the patient face and being operable to adhesively attach to the patient; wherein the injection axis is parallel to the introducer axis.

## THERAPEUTIC AGENT INJECTION DEVICE

#### TECHNICAL FIELD

The technical field of this disclosure is personal medical 5 systems, particularly, therapeutic agent injection devices.

#### BACKGROUND OF THE INVENTION

Certain medical conditions or diseases require that patients 10 intermittently inject a drug or therapeutic agent subcutaneously to maintain the medical condition or disease under control. Multiple daily injections (MDIs) may be required. One such medical condition is diabetes, for which insulin is injected to regulate blood glucose. An estimated twenty-six 15 million people in the United States, or about 8% of the population, have diabetes. This percentage is expected to increase in the near-term as the population ages.

Certain patients are unlikely or unable to follow the drug regimen required to maintain their medical condition under 20 control. Some patients are squeamish about injecting the drug themselves and others suffer adverse effects from repeated injections, such as bruising at the injection site. To accommodate such patients, injection ports have been developed which only require that the patient puncture their skin every 25 few days to install an injection port, rather than injecting with a needle into their skin numerous times a day. Injection ports employ a cannula inserted subcutaneously, and the patient injects the drug into the injection port adhering to their skin rather than directly into their cutaneous tissue.

A new problem arises with damage to the injection port itself. When the injection needle strikes the injection port's cannula, the cannula may be damaged so that the delivery of the drug is no longer controlled. The drug leaks from the damaged portion of the cannula before reaching the required 35 subcutaneous depth. Although a shorter injection needle can be used to attempt to avoid such problems, such needles may not be locally available, limit flexibility in requiring a certain needle length, and provide no assurance that the patient may not still use a longer needle that damages the injection port. 40

It would be desirable to have a therapeutic agent injection device that would overcome the above disadvantages.

## SUMMARY OF THE INVENTION

One aspect of the invention provides an injection device for delivering a therapeutic agent to a patient, the injection device having a body, the body having a patient face and a port face opposite the patient face, the port face having an introducer port including an introducer channel and an injection port 50 an injection device made in accordance with the invention. including an injection channel, the introducer channel being in fluid communication with the injection channel through a cross channel, the injection channel defining an injection axis; a delivery tube for subcutaneous delivery of the therapeutic agent to the patient, the delivery tube projecting from 55 and being generally perpendicular to the patient face, the delivery tube defining an introducer axis and being in fluid communication with the injection port; and a patch, the patch being attached to the patient face and being operable to adhesively attach to the patient; wherein the injection axis is par- 60 allel to the introducer axis.

Another aspect of the invention provides an injection device for delivering a therapeutic agent to a patient, the injection device having a body, the body having a patient face and an port face opposite the patient face, the port face having 65 an introducer port including an introducer channel and an injection port including an injection channel, the introducer

2

channel being in fluid communication with the injection channel, the injection channel defining an injection axis; a delivery tube for subcutaneous delivery of the therapeutic agent to the patient, the delivery tube projecting from and being generally perpendicular to the patient face, the delivery tube defining an introducer axis and being in fluid communication with the injection port; and a patch, the patch being attached to the patient face and being operable to adhesively attach to the patient; wherein the body has a first body portion including the port face and a second body portion including the patient face, the first body portion and the second body portion being rotatably connected with a flange, the first body portion and the second body portion being independently rotatable about the introducer axis.

Another aspect of the invention provides an injection device for delivering a therapeutic agent to a patient, the injection device having a body, the body having a patient face and an port face opposite the patient face, the port face having an introducer port including an introducer channel and an injection port including an injection channel, the introducer channel being in fluid communication with the injection channel, the injection channel defining an injection axis; a delivery tube for subcutaneous delivery of the therapeutic agent to the patient, the delivery tube projecting from and being generally perpendicular to the patient face, the delivery tube defining an introducer axis and being in fluid communication with the injection port; a patch, the patch being attached to the patient face and being operable to adhesively attach to the patient; and a pop-up indicator disposed in the introducer channel, the pop-up indicator having a normal state when pressure in the introducer channel is normal and an alarm state when pressure in the introducer channel exceeds a predetermined value.

The foregoing and other features and advantages of the invention will become further apparent from the following detailed description of the presently preferred embodiments, read in conjunction with the accompanying drawings. The detailed description and drawings are merely illustrative of the invention, rather than limiting the scope of the invention being defined by the appended claims and equivalents thereof.

#### BRIEF DESCRIPTION OF THE DRAWINGS

FIGS. 1-4 are perspective, section, perspective, and exploded perspective views, respectively, of one embodiment of an injection device made in accordance with the invention.

FIGS. 5A-5C are perspective views of one embodiment of

FIG. 6 is a section perspective view of one embodiment of an injection device made in accordance with the invention.

FIGS. 7-11 are perspective, perspective, section, section, and perspective section views, respectively, of one embodiment of an injection device made in accordance with the invention.

FIGS. 12A-12D are side and section views of needleless pen injectors for use with an injection device made in accordance with the invention.

FIGS. 13A-13F are section views of pop-up indicator ports for use with an injection device made in accordance with the invention.

FIGS. 14A & 14B are perspective views of one embodiment of an injection device made in accordance with the

FIGS. 15-20 are front perspective, top side, left side, bottom side, bottom perspective, and detail views, respectively,

of one embodiment of a body for an injection device made in accordance with the invention.

FIG. 21 is a perspective view of one embodiment of an introducer septum for use in an injection device made in accordance with the invention.

FIG. 22 is a section view of an injection device made in accordance with the invention including the introducer septum of FIG. 21.

FIG. **23** is a perspective view of one embodiment of a septum for use in an injection device made in accordance with <sup>10</sup> the invention.

FIGS. 24A & 24B are top side and section views, respectively, of one embodiment of a septum for use in an injection device made in accordance with the invention.

#### DETAILED DESCRIPTION

FIGS. 1-5C, in which like elements share like reference numbers, are various views of one embodiment of an injection device made in accordance with the invention. The injection device includes an introducer port along an introducer axis and an injection port along an injection axis, with the injection axis being non-collinear with the introducer axis. In this embodiment, the injection axis is at an angle to and intersects with the introducer axis.

FIG. 1 is a perspective view of the injection device 100 including a body 110 and a patch 120 attached to the body 110. The patch 120 is operable to adhesively attach the injection device 100 to a patient (not shown). The body 110 has a port face 112, with an introducer port 130 and an injection 30 port 140 on the port face 112. The introducer port 130 is used to place a delivery tube subcutaneously in the patient. The injection port 140 is used by the patient to inject a therapeutic agent, which as defined herein can be any liquid such as a liquid including a therapeutic agent, drug, diagnostic agent, 35 or the like. The body 110 also includes cutouts 160. Those skilled in the art will appreciate that the introducer port 130 can be too small to be effectively used by a patient for injection, but could be used to inject a therapeutic agent, such as a bolus injection using a mechanically attached device, as 40 desired for a particular application.

FIG. 2 is a section view of the injection device 100, the section bisecting the introducer port 130 and the injection port 140, and includes the introducer axis 134 and injection axis 144. An axis as defined herein generally follows the 45 centerline of an associated channel through an associated port. The body 110 has a port face 112 and a patient face 114. A delivery tube 150 for subcutaneous delivery of the therapeutic agent projects from and is generally perpendicular to the patient face 114. The delivery tube 150 is operably con- 50 nected to the introducer port 130 and defines an introducer axis 134 along the introducer channel 132, the delivery tube 150 being in fluid communication with the injection port 140. The introducer port 130 includes an introducer channel 132, with an introducer port cover 135 and an introducer septum 55 136 disposed in the introducer channel 132. The injection port 140 includes an injection channel 142 defining an injection axis 144 with an injection septum 146 disposed in the injection channel 142. In one embodiment, the introducer septum 136 and/or the injection septum 146 is self sealing, such that 60 each of the septums block fluid flow through the septum after a needle has been put through the septum then removed, preventing fluid flow from the port. In this embodiment, the injection axis 144 is at an angle to and intersects with the introducer axis 134. In one example, the delivery tube 150 is a flexible cannula and a needle hub assembly can be used to place the delivery tube 150 subcutaneously in the patient. In

4

another example, the delivery tube 150 is a rigid needle and the delivery tube 150 can be placed subcutaneously in the patient with or without a needle hub assembly.

FIG. 3 is a perspective view of the injection device 100 with a needle hub assembly 170. The needle hub assembly 170 includes a needle hub 172 and a needle 174 attached to the needle hub 172. The needle 174 of the needle hub assembly 170 is inserted through the introducer port 130 and through the delivery tube 150 along the introducer axis 134. The needle hub assembly 170 can be used to add rigidity to the delivery tube 150 during implantation when the delivery tube 150 is a flexible cannula.

FIG. 4 is an exploded perspective view of the injection device with a needle hub assembly. A needle guard 176 disposed around the needle 174 can be used to protect the needle 174 and the delivery tube 150 when the injection device and needle hub assembly are assembled for shipping. The various parts of the injection device and needle hub assembly can be connected by interference fit, adhesive, welding, and/or any other method of attachment suitable for a particular application.

FIGS. 5A-5C are perspective views of various applications of the injection device made in accordance with the invention. Referring to FIG. 5A, a syringe 190 can be used to deliver a 25 therapeutic agent through the injection port 140 of the injection device 100. The syringe can be a conventional syringe, a standard insulin pen, or a needleless syringe. The needle length of a conventional syringe or standard insulin pen can be of any length because the injection axis is non-collinear with the introducer axis, such that a longer needle does not damage the injection device. In one embodiment, the injection port 140 is adapted to be mateable with the syringe 190, with a socket, fitting, or the like, to increase ease of use. In one example, the injection port 140 is a socket with a socket needle which pierces a foil front end of a needleless syringe when the needleless syringe is seated in the socket. The needleless syringe itself has no needle in this example.

Referring to FIG. 5B, an on-body injector 192 is mateable with the injection port 140 of the injection device 100 and can be used to deliver a therapeutic agent through the injection port 140. The on-body injector 192 can include a reservoir to hold the therapeutic agent. In one embodiment, the on-body injector 192 can deliver a basal and/or bolus dose of the therapeutic agent.

Referring to FIG. 5C, an extendable tube 194 can be used to deliver a therapeutic agent through the injection port 140. The extendable tube 194 includes a port connector 195, a tube 196, and an external device fitting 197, all being in fluid communication. The port connector 195 is in fluid communication with the injection port 140 with a needle or mateable fitting to deliver the therapeutic agent through the injection port 140. The external device fitting 197 is connectable to an external device, such as a wearable insulin pump or an infusion tubing line to a gravity fed container.

FIG. 6 is a section perspective view of one embodiment of an injection device made in accordance with the invention. In this embodiment, an upper body portion is rotatable about the introducer axis independent of a lower body portion, so that the injection axis can be positioned at a desired rotary angle regardless of the initial placement of the patch on the patient. This allows the patient to select a rotary position for the injection port that is convenient for injection of the therapeutic agent.

The body of the injection device can have a first body portion including the port face and a second body portion including the patient face, the first body portion and the second body portion being rotatably connected with a flange,

the first body portion and the second body portion being independently rotatable about the introducer axis.

The body 210 of the injection device 200 includes an upper body portion 202 and a lower body portion 204. The upper body portion 202 and lower body portion 204 are rotatably 5 connected with a flange 206 so that the upper body portion 202 and the lower body portion 204 can rotate independently about the introducer axis 234 defined by the delivery tube 250 along the introducer channel 232. The upper body portion 202 has a port face 212 and the lower body portion 204 has a 10 patient face 214. A patch 220 is attached to the patient face 214 and is operable to adhesively attach the injection device 100 to a patient (not shown).

The delivery tube **250** for subcutaneous delivery of a therapeutic agent projects from and is generally perpendicular to the patient face **214**. The delivery tube **250** is operably connected to the introducer port **230**, the delivery tube **250** being in fluid communication with the injection port **240**. The introducer port **230** includes an introducer channel **232**, with an introducer septum **236** disposed in the introducer channel **242** defining an injection axis **244** with an injection septum **246** disposed in the injection channel **242**.

The injection axis 244 is non-collinear with the introducer axis 234. In this embodiment, the injection axis 244 is at an 25 angle to and intersects with the introducer axis 234. In one example, the delivery tube 250 is a flexible cannula and a needle hub assembly can be used to place the delivery tube 250 subcutaneously in the patient. In another example, the delivery tube 250 is a rigid needle and the delivery tube 250 can be placed subcutaneously in the patient with or without a needle hub assembly.

In operation, the patch 220 is attached to the patient and the delivery tube 250 inserted in the patient for subcutaneous delivery of a therapeutic agent. The injection port 240 in the 35 upper body portion 202 can be rotated about the introducer axis 234 even though the lower body portion 204 is at a fixed position on the patient since the lower body portion 204 is attached to the patient by the patch 220.

FIGS. 7-11, in which like elements share like reference 40 numbers, are various views of one embodiment of an injection device made in accordance with the invention. The injection device includes an introducer port along an introducer axis and an injection port along an injection axis, with the injection axis being non-collinear with the introducer axis. In 45 this embodiment, the injection axis is parallel to and does not intersect with the introducer axis.

The injection device for delivering a therapeutic agent to a patient can include a body, the body having a patient face and a port face opposite the patient face, the port face having an 50 introducer port including an introducer channel and an injection port including an injection channel, the introducer channel being in fluid communication with the injection channel through a cross channel, the injection channel defining an injection axis; a delivery tube for subcutaneous delivery of the 55 therapeutic agent to the patient, the delivery tube projecting from and being generally perpendicular to the patient face, the delivery tube defining an introducer axis and being in fluid communication with the injection port; and a patch, the patch being attached to the patient face and being operable to adhesively attach to the patient; wherein the injection axis is parallel to the introducer axis.

FIG. 7 is a perspective view of the injection device 300 including a body 310 and a patch 320 attached to the body 310. The patch 320 is operable to adhesively attach the injection device 300 to a patient (not shown). The body 310 has a port face 312, with an introducer port 330 on the port face 312.

6

The introducer port 330 is used to place a delivery tube subcutaneously in the patient. In this example, an optional injection cap 302 secured to the body 310 to protect an injection port, which is used by the patient to inject a therapeutic agent.

FIG. 8 is a perspective view of the injection device 300 with the optional injection cap removed to expose the injection port 340. In this example, the body 312 includes threads 306 to secure the optional injection cap to the body and an optional O-ring 304 to seal the area around the injection port 340 when the optional injection cap is secured to the body.

FIG. 9 is a section view of the injection device 300, the section bisecting the introducer port 330 and the injection port 340 and including the introducer axis 334 and injection axis 344. The body 310 has a port face 312 and a patient face 314. A delivery tube 350 for subcutaneous delivery of the therapeutic agent projects from and is generally perpendicular to the patient face 314. The delivery tube 350 is operably connected to the introducer port 330 and defines an introducer axis 334 along the introducer channel 332, the delivery tube 350 being in fluid communication with the injection port 340. The introducer port 330 includes an introducer channel 332, with an introducer septum 336 disposed in the introducer channel 332. The injection port 340 includes an injection channel 342 defining an injection axis 344 with an injection septum 346 disposed over the injection channel 342. In this embodiment, the injection axis 344 is parallel to and does not intersect with the introducer axis 334. A cross channel 343 connects the injection channel 342 to the introducer channel 332. In one example, the delivery tube 350 is a flexible cannula and a needle hub assembly can be used to place the delivery tube 350 subcutaneously in the patient. In another example, the delivery tube 350 is a rigid needle and the delivery tube 350 can be placed subcutaneously in the patient with or without a needle hub assembly.

FIG. 10 is a section view of the injection device 300 with a needle hub assembly 370 and a needle guard 376. The needle hub assembly 370 includes a needle hub 372 and a needle 374 attached to the needle hub 372. The needle 374 of the needle hub assembly 370 is inserted through the introducer port 330 and through the delivery tube 350 along the introducer axis 334. The needle hub assembly 370 can be used to add rigidity to the delivery tube 350 when the delivery tube 350 is a flexible cannula. The needle hub assembly 370 can optionally be used when the delivery tube 350 is a rigid needle. A needle guard 376 disposed around the needle 374 can be used to protect the needle 374 and the delivery tube 350 when the injection device and needle hub assembly are assembled for shipping.

FIG. 11 is a perspective section view of the injection device with an injection adapter assembly. For clarity of illustration, the cross section cut of the injection device 300 in the illustration bisects the introducer port 330 and the injection port 340, and includes the introducer axis 334 and injection axis 344. The cross section cut of the injection adapter assembly 400 in the illustration includes the injection axis 344 and is perpendicular to the section of the injection device 300. The injection adapter assembly 400 screws onto the injection device 300 using the threads 306 on the body 310 to secure the needleless pen injector to the body 310, with the O-ring 304 sealing around the interface between the adapter septum 420 and the injector septum 346. Those skilled in the art will appreciate that the mateable connection securing the needleless pen injector to the body is not limited to threads and can be any mateable connection desired for a particular applica-

In this embodiment, the injection adapter assembly 400 is adapted to receive a needleless pen injector (not shown). The adapter body 410 defines a recess 412 adapted to receive a tip of the needleless pen injector. In this example, the needleless pen injector includes threads on its outer diameter complementary to the adapter threads 414 on the inner diameter of the adapter body 410. The tip of the needleless pen injector is screwed into the recess 412 so that the adapter needle 416 is received in the needleless pen injector, accessing the therapeutic agent contained within the needleless pen injector by piercing a foil on the tip of the needleless pen injector or accessing a pen injector port adapted to receive the adapter needle 416. With the needleless pen injector secured in the injection adapter assembly 400, pressure applied to the therapeutic agent enclosed in the needleless pen injector forces the 15 therapeutic agent through the adapter needle 416 and the adapter septum 420 into the injection device 300, where the therapeutic agent passes through the injector septum 346 into the injection port 340, through the injection channel 342, the cross channel 343, and the delivery tube 350, and into the 20

Those skilled in the art will appreciate that a variety of interfaces can be used between the needleless pen injector, the injection adapter assembly 400, and the injection device 300. injector septum 346 are permeable so that the therapeutic agent passes through the adapter septum 420 and the injector septum 346. The septums can be hydrophilic when used with the needleless pen injector to allow the therapeutic agent to pass through. In another embodiment, the injector septum can 30 include a slit valve operable to open on receiving a stub tube at the tip of the needleless pen injector. In yet another embodiment, the injector septum can include a slit valve which is open by a mechanical lever that pushes open and spread the slit valve when the needleless pen injector is received in the 35 injection adapter assembly. In yet another embodiment, the needleless pen injector is interlocked with the injection adapter assembly so that no therapeutic agent can be dispensed from the needleless pen injector until the needleless pen injector is fully engaged with the injection adapter assem- 40 bly.

FIGS. 12A-12D are various views of needleless pen injectors for use with an injection device made in accordance with the invention. Each of the needleless pen injectors is provided with a manual or automatic pressurization to force the thera-45 peutic agent held within the needleless pen injector into the injection device and patient, once the needleless pen injector has been fully engaged with an injection adapter assembly.

FIG. 12A is a side view of the tip of a needleless pen injector 500 having a barrel 502 to contain a therapeutic agent 50 and optional threads 504 for use with an adapter body having threads on the inner diameter. The end 506 of the needleless pen injector 500 can be adapted to accommodate the particular design of an injection adapter assembly for a particular application. FIG. 12B is a section view of the tip of a needle- 55 less pen injector 510 having a barrel 512 to contain a therapeutic agent and a foil 516 across the end of the needleless pen injector 510. The foil 516 can be pierced by an adapter needle in the injection adapter assembly (shown in FIG. 11) to provide fluid communication between the needleless pen injector 60 510 and the injection device through the injection adapter assembly. FIG. 12C is a section view of the tip of a needleless pen injector 520 having a barrel 522 to contain a therapeutic agent and a pen port 526 at the end of the needleless pen injector 520. The pen port 526 can receive an adapter needle 65 in the injection adapter assembly (shown in FIG. 11) to open the pen port 526 and provide fluid communication between

the needleless pen injector 520 and the injection device through the injection adapter assembly. FIG. 12D is a section view of the tip of a needleless pen injector 530 having a barrel 532 to contain a therapeutic agent and a stub tube 536 at the end of the needleless pen injector 530. The stub tube 536 is operable to open a slit valve on the injector septum of the injection device.

FIGS. 13A-13F, in which like elements share like reference numbers, are section views of pop-up indicator ports for use with an injection device made in accordance with the invention. Because the introducer port and the injection port of the injection device are both in fluid communication with the delivery tube, flow blockage in the delivery tube can cause an increase in pressure at both ports when the patient attempts to inject a therapeutic agent. The flow blockage/pressure increase can be detected by the patient, indicating that the therapeutic agent is not being delivered, with a pop-up indicator port in the port not being used for injection. During injection, the membrane of the pop-up indicator port is close to the body of the injection device under normal conditions. and extends from the body of the injection device when the delivery tube is blocked and the pressure increases above a predetermined pressure.

The pop-up indicator can be disposed in the introducer In the embodiment of FIG. 11, the adapter septum 420 and the 25 channel, the pop-up indicator having a normal state when pressure in the introducer channel is normal and an alarm state when pressure in the introducer channel exceeds a predetermined value.

> FIGS. 13A & 13B are section views of a pop-up indicator port 600 with a folded membrane 602 installed as the introducer port. The pop-up indicator port 600 is installed in the introducer channel 632 of the body 610 along the introducer axis 634, and is in fluid communication with the injection channel. A self-closing port 604 in the membrane 602 allows a needle of a needle hub assembly to pass through the membrane 602 when a needle hub assembly is used to implant the injection device. No self-closing port is required if a needle hub assembly is not used to implant the injection device. Referring to FIG. 13A, the pop-up indicator port 600 is in the normal state with normal pressure in the introducer channel 632, with the membrane 602 folded on itself. Referring to FIG. 13B, the pop-up indicator port 600 is in the alarm state due to pressure in the introducer channel 632 exceeding a predetermined value. The pressure occurs when a therapeutic agent is being injected into the injection port, which is in fluid communication with the introducer channel 632, while the delivery tube is blocked. In the alarm state, the membrane 602 unfolds to extend from the body 610.

> FIGS. 13C & 13D are section views of a pop-up indicator port 600 with an accordion membrane 612 installed as the introducer port. Referring to FIG. 13C, the pop-up indicator port 600 is in the normal state with normal pressure in the introducer channel 632, with the membrane 612 pleated like an accordion. Referring to FIG. 13D, the pop-up indicator port 600 is in the alarm state due to pressure in the introducer channel 632 exceeding a predetermined value. The pressure occurs when a therapeutic agent is being injected into the injection port, which is in fluid communication with the introducer channel 632, while the delivery tube is blocked. In the alarm state, the membrane 612 uncompresses the pleats to extend from the body 610.

> FIGS. 13E & 13F are section views of a pop-up indicator port 600 with a deformable membrane 622 installed as the introducer port. Referring to FIG. 13E, the pop-up indicator port 600 is in the normal state with normal pressure in the introducer channel 632, with the membrane 622 extending across the introducer channel 632. Referring to FIG. 13F, the

pop-up indicator port **600** is in the alarm state due to pressure in the introducer channel **632** exceeding a predetermined value. The pressure occurs when a therapeutic agent is being injected into the injection port, which is in fluid communication with the introducer channel **632**, while the delivery tube 5 is blocked. In the alarm state, the material of the membrane **622** deforms under pressure to extend from the body **610**. In another embodiment, the material of the membrane **622** can deforms sufficiently to allow the therapeutic agent to leak through the membrane **622**, providing additional indication 10 of the high pressure and delivery tube blockage.

Those skilled in the art will appreciate that the material and dimensions of the parts of the membrane (folds and/or pleats) can be selected as desired for a particular application. In one embodiment, the material is resilient, so that the membrane 15 returns to the normal state after being in the alarm state. In another embodiment, the material is deformable so that the membrane remains extending from the body after the pressure is relieved and the alarm state clears. The extended membrane reminds the patient of the delivery tube blockage 20 and the need to replace the injection device. Exemplary materials for the membrane include silicone rubber or the like.

FIGS. **14**A & **14**B, in which like elements share like reference numbers, are perspective views of one embodiment of an injection device made in accordance with the invention. In 25 this embodiment, the injection device includes a tube with an external device fitting, so that the injection device can be placed in a remote location and attached to an injection pump.

FIG. 14A is a perspective view of the injection device 700 in a stored configuration, the injection device 700 including a 30 body 710 and a patch 720 attached to the body 710. The patch 720 is operable to adhesively attach the injection device 700 to a patient (not shown). The body 710 has a groove 702 around its outer circumference operable to receive tube 794 in the stored configuration. One end of the tube 794 is in fluid 35 communication with an injection port (not shown) of the injection device 700 to deliver a therapeutic agent into the body of a patient. The other end of the tube 794 is in fluid communication with the external device fitting 797, which can be extended to a convenient location when the injection 40 device 700 is in a difficult to access location or which can be connected to an injection pump (not shown). In this example, the body 710 includes a fitting receiver 704 operable to receive and store the external device fitting 797 when the injection device 700 is in the stored configuration with the 45 tube 794 wrapped around the body 710. FIG. 14B is a perspective view of the injection device 700 in a deployed configuration, with the external device fitting 797 uncoupled from the fitting receiver 704 and the tube 794 uncoiled from the groove 702 in the body 710. In operation, the injection 50 device 700 can be placed on a remote location on the body of the patient, such as a remote location not normally accessible for injection by conventional means, and the tube 794 extended to allow convenient connection to an injection

FIGS. **15-20**, in which like elements share like reference numbers, are various views of one embodiment of a body for an injection device made in accordance with the invention. The body includes cutouts to provide inspection and ventilation at the attachment point of the injection device to the 60 patient.

The single piece body for an injection device can include a planar deck having a patient face, the planar deck having cutouts around and through the planar deck, the planar deck including a delivery tube port on the patient face; a port 65 segment attached opposite the patient face of the planar deck, the port segment including an introducer port including an

10

introducer channel and an injection port including an injection channel the introducer channel being in fluid communication with the injection channel and the delivery tube port; and attachment projections protruding from the patient face. In one embodiment, the attachment projections are operable for plastic welding.

The single piece body can be used with an injection device for delivering a therapeutic agent to a patient including the single piece body. The injection device further includes a delivery tube for subcutaneous delivery of the therapeutic agent to the patient, the delivery tube projecting from and being generally perpendicular to the patient face, the delivery tube being in fluid communication with the injection port; and a patch, the patch being plastically welded to the attachment projections and being operable to adhesively attach to the patient.

FIGS. 15 & 16 are a front perspective view and a top side view, respectively, of a body 810 including a port face 812. The port face 812 includes an introducer port 830 and an injection port 840. The body 810 has a generally planar deck 804 with cutouts 860 spaced around and passing through the planar deck 804. The body 810 also has a port segment 806 rising above the planar deck 804 and including the introducer port 830 and an injection port 840. The body 810 is a single piece body, which is defined herein as a body formed as a single piece and is not a group of separate pieces assembled to form the body.

FIG. 17 is a left side view of the body 810. The patient face 814 is opposite the port face 812 on the planar deck 804 and is operable to connect the body 810 to a patch (not shown) to adhesively attach the injection device to a patient. In this embodiment, the patient face 814 of the planar deck 804 includes a number of attachment projections 820 (in this example, the attachment projections 820 being bumps) protruding from the planar deck 804 to allow a patch to be plastically welded to the body 810. Those skilled in the art will appreciate that different attachment projections, such as truncated pyramids, bumps, radial lines, concentric rings, or the like, can be selected as desired for a particular application. In yet another embodiment, the patch can be attached to the body 810 with an adhesive.

FIGS. 18 & 19 are a bottom side view and a bottom perspective view, respectively, of the body 810. The attachment projections 820 are arranged around the outer circumference 823 of the patient face 814, around an inner circle 822 about a delivery tube port 825 on the introducer axis 834, and along diameter segments 824 between the outer circumference 823 and the inner circle 822 which follow the length of the port segment. In this example, the attachment projections 820 are truncated pyramids.

FIG. 20 is a section view of the planar deck 804 of the body **810** along the outer circumference through the attachment projections 820. In this example, the body 810 is plastically welded to a patch 830, which is attached to the skin 832 of a patient. The attachment projections 820 are deformed from the truncated pyramid to a flattened, rounded shape from welding the attachment projections 820 to the patch 830 at each fixation point 836. In this example, the tips of the attachment projections 820 are welded into the patch 830, i.e., the tips of the attachment projections rest below the surface of the patch at the fixation points 836 where the attachment projections 820 join the patch 830. In cross section through adjacent attachment projections 820, the patient face 814 and the patch 830 define a ventilation gap 838 to provide ventilation and air circulation between the planar deck 804 and the patch 830, cooling the skin 832 across the patch 830 from the ventilation gap 838.

Those skilled in the art will appreciate that the design of the patch 830 can be selected as desired for a particular application. The patch can be made of any biocompatible material with biocompatible adhesive operable to hold the weight of the injection device to the skin for a predetermined number of 5 days. The patch design also needs to account for ventilation and circulation between the patch and the skin. In one example, the patch is a continuous sheet of adhesive material. In another example, the patch is a mesh sheet of adhesive material including perforations. In yet another example, the patch is a continuous sheet of adhesive material with holes cut into the continuous sheet. The holes can align with features of the body of the injection device, such as the cutouts, as desired. The holes can optionally be the same size as the cutouts. In yet another example, the patch is a continuous 15 sheet of adhesive material with holes cut into the continuous sheet, and mesh applied across the holes. In yet another example, the patch can be made of a transparent material to allow the condition of the skin around and below the injection device to be monitored. In one example, adhesive patches are 20 constructed of pressure sensitive acrylic-based adhesives with non-woven polyester backings.

Those skilled in the art will further appreciate that the design of the body of the injection device can be selected as desired for a particular application. In one example, the num- 25 ber and position of the cutouts in the planar deck can be selected to provide ventilation to the skin while maintaining sufficient rigidity for the planar deck. In another example, the number and position of the cutouts can be selected to allow observation of the condition of the skin around and below the 30 injection device. In yet another example, the body of the injection device can be made of a transparent material to allow the condition of the skin around and below the injection device to be monitored. This is particularly useful when the patch includes holes or is made from a transparent material. 35 Exemplary materials for the body of the injection device include polycarbonate, acrylic, or the like. In one embodiment, one or more optical elements can be molded into the body of the injection device to magnify the area or areas of

FIGS. **21-24** are various embodiments of septums for use in an injection device. The septums can be disposed in the injection device channels. In one embodiment, the septum is self sealing to block fluid flow through the septum after a needle has been put through the septum then removed, preventing fluid flow through the port connected to the channel.

FIG. 21 is a perspective view of one embodiment of an introducer septum for use in an injection device made in accordance with the invention. In this embodiment, the introducer septum is irregular-shaped, i.e., the introducer septum 50 has an irregular shape. The introducer septum 900 includes a number of legs 902 to secure the introducer septum 900 in the introducer channel.

FIG. 22 is a section view of an injection device made in accordance with the invention including the introducer septum of FIG. 20. The section bisects the introducer port 930 and the injection port 940, and includes the introducer axis 934 and injection axis 944. The delivery tube 950 is operably connected to the introducer port 930 and defines an introducer axis 934, the delivery tube 950 being in fluid communication with the injection port 940. The introducer port 930 includes an introducer channel 932, with an introducer port cover 935 and the introducer septum 900 disposed in the introducer channel 932. The introducer septum 900 is secured in the introducer channel 932 of the injection device 901 by legs 65 902. The injection port 940 includes an injection channel 942 defining an injection axis 944 with an injection septum 946

12

disposed in the injection channel 942. The injection channel 942 is in fluid communication with the delivery tube 950 through a septum connection channel 904 in the introducer septum 900. The introducer septum 900 both connects the injection port 940 to the delivery tube 950 and fills extra space within the introducer channel 932 to avoid an unnecessary amount of therapeutic agent from collecting in the introducer channel 932.

FIG. 23 is a perspective view of one embodiment of a septum for use in an injection device made in accordance with the invention. In this embodiment, the septum is barrel-shaped. The barrel-shape septum 980 can be used as an introducer septum or an injection septum as desired for a particular application.

FIGS. **24**A & **24**B are top side and A-A section views, respectively, of one embodiment of a septum for use in an injection device made in accordance with the invention. In this embodiment, the septum is dome-shaped. The dome septum **990** can be used as an introducer septum or an injection septum as desired for a particular application.

It is important to note that FIGS. 1-24 illustrate specific applications and embodiments of the invention, and are not intended to limit the scope of the present disclosure or claims to that which is presented therein. Upon reading the specification and reviewing the drawings hereof, it will become immediately obvious to those skilled in the art that myriad other embodiments of the invention are possible, and that such embodiments are contemplated and fall within the scope of the presently claimed invention.

While the embodiments of the invention disclosed herein are presently considered to be preferred, various changes and modifications can be made without departing from the spirit and scope of the invention. The scope of the invention is indicated in the appended claims, and all changes that come within the meaning and range of equivalents are intended to be embraced therein.

The invention claimed is:

- 1. An injection device for delivering a therapeutic agent to a patient, the injection device comprising:
  - a body having a patient face and a port face opposite the patient face, the port face having an introducer port including an introducer channel and an injection port including an injection channel, the introducer channel being in fluid communication with the injection channel, the injection channel defining an injection axis;
  - a delivery tube for subcutaneous delivery of the therapeutic agent to the patient, the delivery tube projecting from and being generally perpendicular to the patient face, the delivery tube defining an introducer axis and being in fluid communication with the injection port;
  - a patch attached to the patient face and operable to adhesively attach to the patient; and
  - an injection adapter assembly removably connected to the injection port, the injection adapter assembly receiving a needleless pen injector:
  - wherein the body has a first body portion including the port face and a second body portion including the patient face, the first body portion and the second body portion being rotatably connected with a flange, the first body portion and the second body portion being independently rotatable about the introducer axis.
  - 2. The injection device of claim 1 wherein the body and the needleless pen injector have complementary threads operable to secure the needleless pen injector to the body.
  - 3. The injection device of claim 1 wherein the injection adapter assembly includes a recess to receive the needleless

pen injector, the recess and the needleless pen injector having complementary threads operable to secure the needleless pen injector within the recess.

- 4. The injection device of claim 1 wherein the injection adapter assembly includes a recess to receive the needleless 5 pen injector, the recess including an adapter needle operable to access the therapeutic agent contained within the needleless pen injector.
- **5**. The injection device of claim **4** wherein the needleless pen injector has an end with a foil across the end, the foil 10 being pierceable by the adapter needle.
- 6. The injection device of claim 4 wherein the needleless pen injector has an end with a pen port disposed in the end, the pen port being openable by the adapter needle.
- 7. The injection device of claim 1 further comprising a 15 pop-up indicator disposed in the introducer channel, the pop-up indicator having a normal state when pressure in the introducer channel is normal and an alarm state when pressure in the introducer channel exceeds a predetermined value.
- **8**. The injection device of claim **7** wherein the pop-up 20 indicator includes a self-closing port operable to receive a needle of a needle hub assembly.
- **9**. The injection device of claim **7** wherein the pop-up indicator has a membrane selected from the group consisting of a folded membrane, an accordion membrane, and a 25 deformable membrane.
